

## Motivation

The motivation behind our project was to educate people about something that affects us all - politics. Once we knew we wanted politicians to be one of our models, we determined the other two should be states and news sources. States correlate well with politicians and the news is how we keep up with them. We want our users to be able to educate themselves about not only their state and representatives, but any of them that peak their curiosity. We are designing our website to be user friendly so that anyone can use it. A better understanding of our nation and the people running it will lead to a better present and an even greater future.

## User Stories

### Phase I User Stories

- **“More horizontal state instance page:** As a user, I would like to see the state pages be formatted more horizontally. Right now the state instance pages' information are stacked vertically, which is a bit hard for the user to read. It could have, for example, have multiple images on around the same level, have the state flag on the top left hand side, the state senators on the top right hand side, and the state map beneath the two. Any way is fine, right now it is a little difficult to read.”
  - This was implemented by using cards in rows to display state information.
- **“Detailed News Model Page:** As a user, I would like to see more info about each news source in the grid, rather than just a logo. This would be helpful in quickly gathering more info about a news source before deciding whether to investigate it further or not.”
  - This was implemented by adding additional data, such as “year founded” and “number of employees” to each news source in the grid.
- **“Democrat/Republican color coordination:** As a user, I would like to have some sort of color coordination for parties for the politician model page so that users are more prepared for what they will click on. For example, you could have a party column in your table that has a red square/text for republicans and a blue one for democrats (and something else for others). I think that will really help with clarity for distinguishing politicians, and would be useful to sort by in the future.”
  - This was implemented by adding an image for each party in the table.
- **“More Welcoming Splash Page:** Currently when going on the website, the vibe doesn't seem very welcoming or have a political theme besides the huge picture

of Ted Cruz. As a user I'd like to see A nicer theme since this is the first impression the user will get."

- This was implemented by adding different images, cards, and links to the Splash page.
- **"Twitter feed for politicians:** As a user of your website, I would like to see a Twitter feed for each politician or even a few tweets (such as most liked, most retweeted, etc.). As of now, the politician pages display only the number of tweets, which doesn't seem helpful. I think the politician tweets would be an informative feature for the page."
  - This was implemented by using Reacted Twitter Embed Component, which allowed for a twitter feed for each politician as well as a link to "tweet at" them.

### Phase I Customer Stories

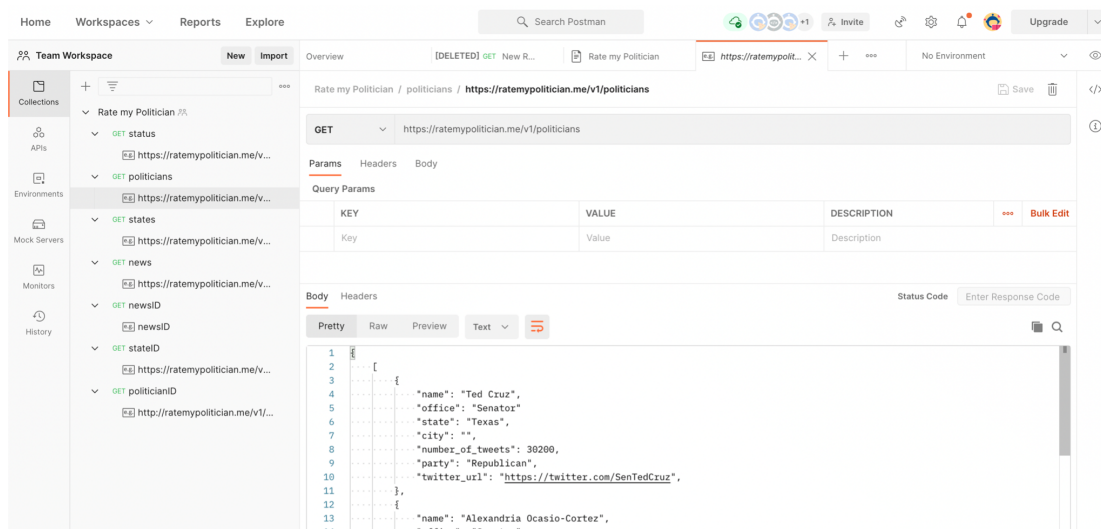

- **"Collect Data on Many Instances of Each Model:** As a user, I would like more than 3 instances of each model. These instances should collect data from sources with a RESTful API."
- **"Style/Color of website:** As your client, I want the website to have more vibrant colors rather than a darker tone. This can be anything that you guys choose. However, an idea I had was when stocks are trending downwards indicate those with red and when they're trending upwards indicate those with green."
- **"Congress Member Stock Positions as a Page:** As a user, I would like to have a "Congress member stock positions" page that I can access through the navbar. This could be in the form of a table, or any form that presents the data clearly."
- **"Campaign Finances Page: Add States and Positions:** As a user, I would like to see information on a politician's current position and state affiliation on their card on the Campaign Finance model page. For example, underneath "T. J. Ossoff" and above "Total Received" would be the words "Georgia Senator". This is because many people don't know the names of all politicians in congress but would be able to recognize their titles."
- **"Government Models Data:** As a user, I would like to see a grid or table of government contracts. The data for this page should be fetched from your REST API. The data in this grid or table should also be paginated."

## REST API

The design of our RESTful API was done using Postman, a tool that provides testing and documentation capabilities for APIs. For each endpoint that we anticipate implementing in our RESTful API, we defined a number of attributes, including:

- The endpoint name
- The endpoint url
- A description of the purpose of the endpoint
- An example request
- An example response

Editing a example response:

In order to document the API collaboratively, a shared team was created in Postman. In this shared workspace, we then created a collection called “Rate My Politician” to contain the endpoints. We then were able to add each endpoint and its information as well as a sample request. The following endpoints were documented:

- All politicians
  - This endpoint returns a json response with all politicians in the database. It is used for rendering the politicians model page.
  - <https://ratemypolitician.me/api/politicians>
- All states
  - This endpoint returns a json response with all states in the database. It is used for rendering the states model page.
  - <https://ratemypolitician.me/api/states>
- All news sources
  - This endpoint returns a json response with all news sources in the database. It is used for rendering the news sources model page.

- <https://ratemypolitician.me/api/sources>
- A single politician by id
  - This endpoint returns a json response with a single politician. It is used to render single instances of politicians.
  - <https://ratemypolitician.me/api/politicians/<id>>
- A single state by id
  - This endpoint returns a json response with a single state. It is used to render single instances of states.
  - <https://ratemypolitician.me/api/states/<id>>
- A single news source by id
  - This endpoint returns a json response with a single news source. It is used to render single instances of news sources.
  - <https://ratemypolitician.me/api/sources/<id>>
- A single politician by name
  - This endpoint returns a json response with a single politician. It is used to query the backend for a politician.
  - <https://ratemypolitician.me/api/politicians/<name>>
- A single state by name
  - This endpoint returns a json response with a single state. It is used to query the backend for a state.
  - <https://ratemypolitician.me/api/states/<name>>
- A single news source by name
  - This endpoint returns a json response with a single news source. It is used to query the backend for a news source.
  - <https://ratemypolitician.me/api/sources/<name>>

The api documentation can be found at this link:

<https://documenter.getpostman.com/view/12075941/Tz5jeLVC>

## Models

Our Project #2 agenda is to create a website where users can learn about how various news sources and social media cover politicians in the US. To account for the social media/news aspect, we decided to combine a news and twitter apis to form a News Sources Model. Politicians are a key factor for the website goal, so we decided on a Politicians Model based on a civic information api to create a database of US politicians. Lastly, since every politician is affiliated with a state, we decided on a State Model so users can keep up with politicians in their state and keep up with news stories about political figures prevalent to their everyday lives.

The Structure of the Models are as follows:

**News Sources Model:**

Instance: News Sources that cover politics

Attributes:

- Name
- Logo
- Number of Employees
- Year Founded
- City
- State
- Alexa company rank
- Twitter bio
- Twitter followers
- Organization type
- Description

APIs: <https://newsapi.org>  
<https://bigpicture.io/docs/enrichment/company/>

Model Page Layout: The model page is designed so that the news logos are visible in a grid. Clicking on the image will lead to the individual instances pages for each news source. This layout was chosen because most users will recognize news sources by their logos before their names.

Instance Page Layout: Currently, each instance page contains the New Source instance's name, logo, and list of attributes.

**Politicians Model:**

Instance: US Politicians

Attributes:

- Name
- State
- Political party
- Position
- Number of tweets
- Twitter url
- Number of articles
- Phone number
- Email address

- Website url

API: <https://developers.google.com/civic-information>

Model Page Layout: The model page is designed so the user sees a large table, where the rows are politicians. The information given for each politician includes their headshot, first name, last name, and link to their respective instance pages. This design was chosen because many people only know either the position title, name, or image of a politician but it is unlikely that they will know all three. So, all information is provided so they can quickly identify who they're looking for based on what they know.

Instance Page Layout: Currently, each instance page contains the politician's name, headshot, link to their social media, and a list of attributes.

### **States Model:**

Instance: US States

#### Attributes:

- Population
- Name
- 2016 election result
- Median income
- Poverty rate
- Governor name
- How many representatives
- Median age
- Median housing price
- Senator names
- State Flag
- State Map
- Articles about the state
- List of senators and governor

API: <https://datausa.io/about/api/>

Model Page: The model page is designed so that the user sees cards assigned to each state in a grid. Each card contains the state's name, map, attributes, and link leading the user to the states' instance page. This design was chosen because most people associate an image of a state with the title, so by having both information available to identify the instance, the page becomes more interactive.

Instance Pages: Currently, each instance page contains the state's name, flag, seal, it's attributes, images of the senators and governor from the state, and current news articles.

### **Connections Between Models:**

- News sources have articles on politicians and cover different states
- Politicians each represent and are affiliated with particular states and have social media accounts
- States are represented by both politicians and news sources

## **Tools**

In phase I, the tools used were mainly for the development of the static site and the design of the RESTful API. Postman was used for the API design as described in the REST API section above.

### ***Create React App***

For building the static site, a number of tools were used to create a frontend client. Create React App, a toolchain aimed at creating and managing React applications, was used to create the frontend client. In order to create the application, the following script was run:

```
npx create-react-app rmp-frontend
```

### ***React Router***

For each page in the static site, a new React component was created, with some pages rendering multiple React components. In order to route between different pages in the site, the React Router library was used which allows the programmer to define routes and create links to those routes across pages. For example, a portion of the routing mechanism is displayed below:

```
<Switch>
  <Route path="/about" component={About} />
  <Route path="/news" component={News} />
  ...
</Switch>
```

### ***React Bootstrap***

In order to handle styles, the React Bootstrap package was used. This package allows the programmer to import pre-styled components to easily build a consistently styled site. Examples of components provided by React Bootstrap used in the static site include buttons, padded containers, tables, cards, image carousels, etc. Using React Bootstrap components is demonstrated below in the Header component:

```
import NavBar from 'react-bootstrap/Navbar';
import Nav from 'react-bootstrap/Nav';
import { Link } from 'react-router-dom';

const Header = () => {
  return (
    <NavBar bg="dark" variant="dark">
      <NavBar.Brand as={Link} to="/">Rate My Politician</NavBar.Brand>
      <Nav>
        <Nav.Link as={Link} to="/about">About</Nav.Link>
        <Nav.Link as={Link} to="/news">News Sources</Nav.Link>
        <Nav.Link as={Link} to="/State">States</Nav.Link>
        <Nav.Link as={Link} to="/politicians">Politicians</Nav.Link>
      </Nav>
    </NavBar>
  );
};

export default Header;
```

### ***Jupyter Lab, Pandas***

In order to scrape and process the data, Jupyter Lab, a web interface for working with Jupyter notebooks was used. This enables us to run python code flexibly and scrape data from the numerous APIs and process it. Pandas, a python package for dealing with data tables, was also used. This enabled us to make uniform tables to store the data scraped from various APIs and format them to be imported to the database.

### ***Flask***

To write the backend server, Flask, a python framework, was used to set up a simple server and define the various endpoints that compose our REST API. In order to

access the database, a connection was defined using the SQL Alchemy connection library for flask. Then, schema were defined for each model using another package called Marshmallow, which allows you to create schema with a defined set of fields. Once this was done, the endpoints were defined and for each one, data from the database was queried, either all the data for a model or a specific instance, filtered using a variable provided in the request url. Below is an example of an endpoint being defined in flask:

```
#Get all States
@app.route('/api/states', methods=['GET'])
def get_states():
    all_states = States.query.all()
    result = states_schema.dump(all_states)
    return jsonify(result)
```

## Hosting

We hosted our website by following the tutorial given at: [How to deploy a website on AWS with Docker, Flask, & React from scratch](#)

However, we did a couple of things a little different so I'll give a more elaborate view of what we did below.

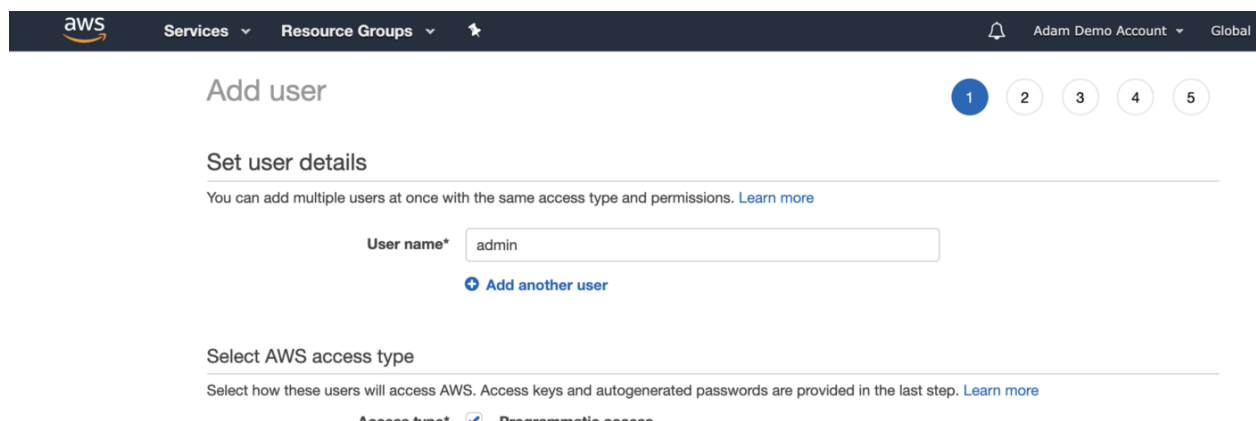

1

We decided to host our website using AWS and we started by creating an account with [Amazon Web Services \(AWS\) - Cloud Computing Services](#).

We then downloaded the aws command line interface which you can find a guide for here : [Installing, updating, and uninstalling the AWS CLI version 2 - AWS Command Line Interface](#)

2

The next step we did was create an AWS user which we did by searching up IAM and going to Users under access management and selecting Add user.

The screenshot shows the AWS IAM console 'Add user' page. The top navigation bar includes the AWS logo, 'Services', 'Resource Groups', and a user profile 'Adam Demo Account'. The page title is 'Add user' with a progress indicator showing 5 steps, with step 1 being the current step. The section 'Set user details' contains a text input for 'User name\*' with the value 'admin' and a button 'Add another user'. Below this is the 'Select AWS access type' section, which includes a note about access keys and passwords, and a radio button for 'Programmatic access'.

Once we went through and reached the Create Group page we chose the one with the Policy name “AdministratorAccess” with the type as Job Function. We stopped once we successfully reached the Success page.

We then configured AWS by typing **aws configure** in the terminal and following the given instructions.

### 3

Next was the deployment of our front end and the first thing we did was create an S3 bucket with AWS to store our frontend files.

## rmp-frontend

[Objects](#)[Properties](#)[Permissions](#)[Metrics](#)[Management](#)[Access Points](#)

### Bucket overview

<b>AWS Region</b> US East (Ohio) us-east-2	<b>Amazon resource name (ARN)</b>  arn:aws:s3:::rmp-frontend
<b>Creation date</b> February 26, 2021, 14:18:39 (UTC-06:00)	

Everything in the bucket had to be public initially. Next we actually built the frontend and pushed it to our bucket using the following commands:

```
cd rmp-frontend
npm run build
aws s3 sync build/ s3://rmp-frontend --acl public-read
```

We also made sure all the files were public so we wouldn't run into any issues.

### 4

Then we finally created a cloudfront CDN deployment. We started by creating a distribution in CloudFront and we linked our S3 bucket and set the origin path to /index.html.

The steps to make the CDN are shown on the next page.

Origin Domain Name	<input type="text" value="rmp-frontend.s3.amazonaws.com"/>					
Origin Path	<input type="text"/>					
Enable Origin Shield	<input type="radio"/> Yes <input checked="" type="radio"/> No					
Origin ID	<input type="text" value="S3-rmp-frontend"/>					
Restrict Bucket Access	<input type="radio"/> Yes <input checked="" type="radio"/> No					
Origin Connection Attempts	<input type="text" value="3"/>					
Origin Connection Timeout	<input type="text" value="10"/>					
Origin Custom Headers	<table><thead><tr><th>Header Name</th><th>Value</th></tr></thead><tbody><tr><td><input type="text"/></td><td><input type="text"/></td></tr></tbody></table>	Header Name	Value	<input type="text"/>	<input type="text"/>	
Header Name	Value					
<input type="text"/>	<input type="text"/>					

### Default Cache Behavior Settings

Path Pattern	<input type="radio"/> Default (*)	
Viewer Protocol Policy	<input checked="" type="radio"/> HTTP and HTTPS <input type="radio"/> Redirect HTTP to HTTPS <input type="radio"/> HTTPS Only	
Allowed HTTP Methods	<input checked="" type="radio"/> GET, HEAD <input type="radio"/> GET, HEAD, OPTIONS <input type="radio"/>	

---

Supported HTTP Versions	<input checked="" type="radio"/> HTTP/2, HTTP/1.1, HTTP/1.0 <input type="radio"/> HTTP/1.1, HTTP/1.0	
Default Root Object	<input type="text" value="index.html"/>	
Standard Logging	<input type="radio"/> On <input checked="" type="radio"/> Off	
S3 Bucket for Logs	<input type="text"/>	
Log Prefix	<input type="text"/>	
Cookie Logging	<input type="radio"/> On <input checked="" type="radio"/> Off	
Enable IPv6	<input checked="" type="checkbox"/> <a href="#">Learn more</a>	
Comment	<input type="text"/>	
Distribution State	<input checked="" type="radio"/> Enabled <input type="radio"/> Disabled	

[Cancel](#) [Back](#)

Once the distribution was done processing we confirmed everything was working by clicking on the domain name which you can find under your CDN distribution under the general tab.

## 5

The final step we had to host our website was to add our custom domain name. The first step was to find the domain which we found at [Namecheap: Buy domain name - Cheap domain names from \\$1.37](#). Once we had the domain name we wanted to use we had to go and create a Hosted zone on Route 53 using the domain name we got from Namecheap.

**Records (6)** [Info](#)  
Automatic mode is the current search behavior optimized for best filter results. [To change modes go to settings.](#)

 **Delete record** **Import zone file** **Create record**

< 1 >

Alias ▼

<input type="checkbox"/>	Record name ▼	Type ▼	Routin... ▼	Differ... ▼	Value/Route traffic to ▼
<input type="checkbox"/>	ratemypolitician.me	A	Simple	-	d1ifca7awssl0y.cloudfront.net.
<input type="checkbox"/>	ratemypolitician.me	NS	Simple	-	ns-566.awsdns-06.net. ns-287.awsdns-35.com. ns-2023.awsdns-60.co.uk. ns-1215.awsdns-23.org.
<input type="checkbox"/>	ratemypolitician.me	SOA	Simple	-	ns-566.awsdns-06.net. awsdns-hos
<input type="checkbox"/>	_df0cc77435e32917...	CNAME	Simple	-	_32ae68c0bb82dfbcab540f4e81d6
<input type="checkbox"/>	www.ratemypoliticia...	CNAME	Simple	-	ratemypolitician.me
<input type="checkbox"/>	_8195ae00197a29df...	CNAME	Simple	-	_c22da443df20f51f19d059df4432

Now in a new tab we went to Namecheap and under the Domain List tab we went to Nameservers and chose Custom DNS and added our NS records from Route 53.

The screenshot shows the Namecheap Domain List interface. On the left is a sidebar with navigation links: Domain List (active), Hosting List, Private Email, SSL Certificates, Apps, and Profile. The main content area is titled 'PremiumDNS' with a question mark icon. It contains a description: 'Enable PremiumDNS protection in order to switch your domain to our PremiumDNS platform. With our PremiumDNS platform, you get 100% DNS uptime and DDoS protection at the DNS level.' and a 'BUY NOW' button. Below this is a section for 'NAMESERVERS' with a question mark icon. It shows a dropdown menu set to 'Custom DNS'. Below the dropdown, there are four text input fields containing the following nameservers: 'ns-1215.awsdns-23.org.', 'ns-2023.awsdns-60.co.uk.', 'ns-287.awsdns-35.com.', and 'ns-566.awsdns-06.net.'. Below these fields is a red button with a plus icon and the text 'ADD NAMESERVER'. At the bottom of the main content area is a section for 'REDIRECT DOMAIN' with a question mark icon. It contains a description: 'You can create redirects via your DNS provider or your Namecheap account. To perform this function from your account, you must first change your nameservers to Namecheap default. [Learn How](#) →'.

From here, we went back to CloudFront and we clicked the edit distribution option and added our new domain names under alternate domain names(CNAMEs). Then we had to request a certificate with ACM as the field will initially be blank and you must wait for it to be validated.

- To do this you select the DNS Validation and choose the option to create a record for the alternate names you added.

**Price Class** Use Only U.S., Canada and Europe ⓘ

**AWS WAF Web ACL** None ⓘ

**Alternate Domain Names (CNAMEs)** ratemypolitician.me

Cancel **Define simple record**

Define simple record

Record type

The DNS type of the record determines the format of the value that Route 53 returns in response to DNS queries.

A – Routes traffic to an IPv4 address and some AWS resources

Choose when routing traffic to AWS resources for EC2, API Gateway, Amazon VPC, CloudFront, Elastic Beanstalk, ELB, or S3. For example: 192.0.2.44.

Value/Route traffic to

The option that you choose determines how Route 53 responds to DNS queries. For most options, you specify where you want to route internet traffic.

Alias to CloudFront distribution

US East (N. Virginia)

d1ifca7awssl0y.cloudfront.net

Evaluate target health

Select **Yes** if you want Route 53 to use this record to respond to DNS queries only if the specified AWS resource is healthy.

No

Cancel

Define simple record

With this both <https://ratemypolitician.me> and <https://www.ratemypolitician.me> worked.

## Pagination

We were able to implement pagination by using the react-bootstrap pagination feature in each of our model pages. For our States and News Sources pages, their instances are displayed in a grid. While our Politicians page has its sources displayed in a table. Above the bar is a feature informing the user of how many instances there are currently for each model. The resulting navigation bar looks as follows:

50 State instances

<<

<

1

2

3

4

5

6

>

>>

The pagination navigation bar was designated to have the following routes:

- << (First) - sending the user to page 1
- < (Prev) - sending the user to the page one before the one they are currently on
- 1...n (List of Page Numbers) - Here we placed all pages available to navigate to in an array so the user can target a specific page

- > (Next) - sending the user to the page one after the one they are currently on
- >> (Last) - sending the user to the very final page generated

A special case we had to make for the Politicians page was shortening the list of page numbers since the large number of instances generated 86 pages. So, we added in a “...” option on the pagination navigation bar after 7 pages.

**The Resulting Statistics for Pagination**

Model Page	Number of Instances per Page	Number of Pages
News Sources	9	12
States	9	6
Politicians	100	86

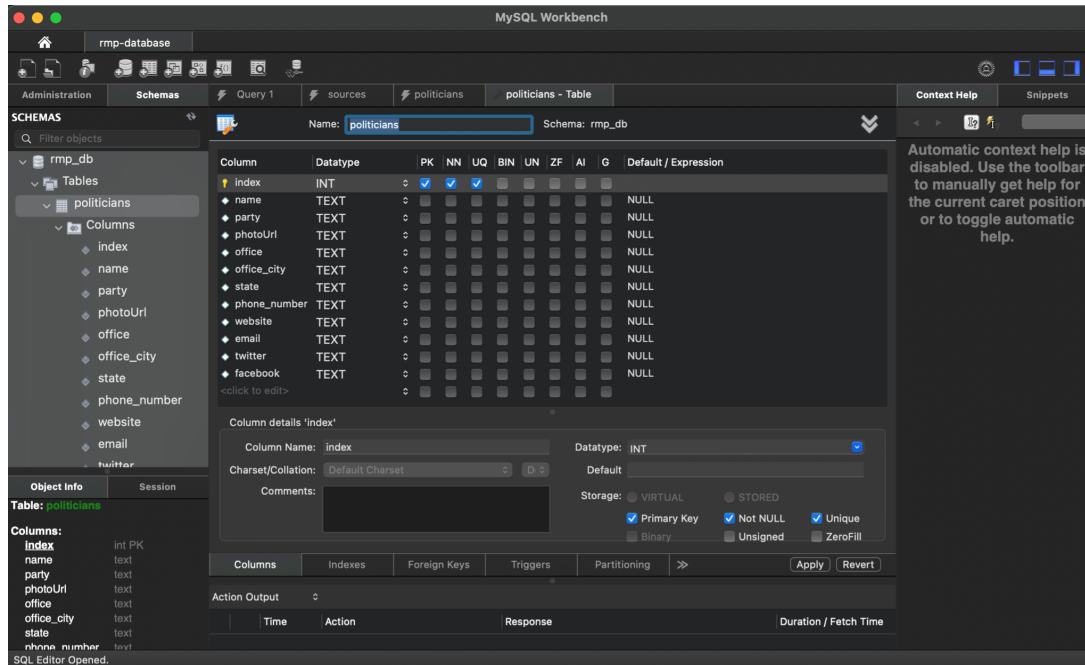

## Database

The database used by the backend to store and retrieve information is a MySQL database hosted on the RDS service on AWS. This service allows you to host a database in the cloud and connect to it from your backend server. The database was set up through this portal in the image on the right. A security profile setting was also modified to allow access from external sources, such as the database client and the backend server.

Once the database was running, we used a database client, MySQL Workbench to load in the data to the database. After having scraped the data and stored it in csv files for each model, the csv data was added to the database as new tables. The column names for each table could then be modified to match the backend. Below is a view of MySQL workbench accessing the metadata for the politicians table:

## Testing

Our testing was implemented in four different parts.

We created unit tests for the RESTful API using Postman, unit tests of the JavaScript using Jest, acceptance tests of the GUI using Selenium, and unit tests of the Python code using unittest. Creating the unit tests for JavaScript using Jest was on the easier side to implement and there is an example of it below. We used this to test our frontend functionality and code.

```
import "@testing-library/jest-dom/extend-expect";
import { render } from "@testing-library/react";
import { BrowserRouter } from "react-router-dom";
import Splash from "../components/Splash/Splash";

test("Splash page renders", () => {
  const component = render(
    <BrowserRouter>
      <Splash />
    </BrowserRouter>
  );

  const element = component.getByText("The REAL Truth");
  expect(element).toBeDefined();
});
```

We used unittest for the tests for the backend and the GUI tests. It is a tool that's commonly used for unit testing for Python as the name would suggest. We see an

example of it being shown below for the backend.

```
import unittest
import json

import app

class APITests(unittest.TestCase):

    def test_get_states1(self):
        all_states = json.loads(app.get_states().data)
        self.assertEqual(len(all_states), 50)

    def test_get_states2(self):
        all_states = json.loads(app.get_states().data)
        fields = ['data_year', 'dem_margin', 'governor_name', 'index', 'landscape_background_url',
        for state in all_states:
            keys = list(state.keys())
            self.assertEqual(keys, fields)

    def test_get_state1(self):
        state = json.loads(app.get_state(0).data)
        self.assertEqual(state['name'], 'Alabama')
```

The unit tests for the RESTful API using Postman was also a straight forward implementation and the documentation for it is found online: [Automated API Testing](#)

However, one part of the testing we struggled with was the GUI testing specifically getting Selenium working. We will go over how we did these tests more thoroughly below.

## Selenium

To get started with testing for selenium, we had to first download a couple of dependencies.

- pip install selenium
- brew install --cask chromedriver (For MacOS)

Once we got the initial dependencies setup, we needed to download a standalone selenium server for us to be able to run the tests locally. The code used to run the tests locally and on the pipeline are different as you can see in the example below along with a few GUI tests.

```

import unittest
import time
from selenium import webdriver
#from selenium.webdriver.common.desired_capabilities import DesiredCapabilities

class GUITests(unittest.TestCase):
    def setUp(self):
        # create a new remote Chrome session
        self.driver = webdriver.Remote(command_executor="http://selenium_standalone-chrome:4444/wd/hub", c
        #For running locally
        # self.driver = webdriver.Remote(
        #     command_executor='http://127.0.0.1:4444/wd/hub',
        #     desired_capabilities=DesiredCapabilities.CHROME)
        self.driver.implicitly_wait(10)
        self.driver.maximize_window()

        # navigate to the application home page
        self.driver.get("http://www.ratemypolitician.me/")

    def tearDown(self):
        self.driver.quit()

```

We have to create a Remote webdriver so that we can run these tests in the pipeline. We use these tests to see if we can find certain elements on our webpage. For example, we check to see if when we navigate to the states page we can find the More Info button.
